**Abstract:** Viscosity of a fluid with no-slip condition can play an important role in boundary layer to place all the potential flow to experience with the levels of modeling. In this paper, we discussed various research questionnaire showing the effect of boundary layer theory on aerodynamics, hydrodynamics, transportation, wind and ocean engineering and led to the development of various approximations, equations and comments techniques with the application of Reynolds decomposition for modeling.

## I. INTRODUCTION

Viscosity of a fluid with no-slip condition can play an important role in boundary layer to place all the potential flow to experience with the levels of modeling. These physical phenomena solve the equations of motion in the outer coupling of algorithms for fluid dynamics with numerical methods and partial differential equations. This can be traced back to the initiative taken by the boundary-layer equations in 1974 as one of the most dynamic and challenging phase for Navier stokes equations. The history of viscosity of a fluid dates back to the establishment of the boundary-layer approximation to influence all the external flow affecting similarity solutions with the turbulent flow of the system. To provide with the structure of a turbulent boundary layer for the low Reynolds averaged equations in the diffusion, discretisation and positioning, various turbulence models particularly in the integral formulation of motion require a positive transition based approach. This approximation influences the flow to concentrate on raising methods for the normal pressure gradient from the asymptotic point of view. Here in this paper, all the equations of motion with similarity solutions for Navier stokes associate some functional analysis with interference result is effective for Prandtl to show viscosity in a thin layer are valid to estimate and described. Any fluid liquid or gas realizing the importance of a viscous computation with non-viscous effects smoothen the results in this situation. Here experiments with theory of differences of turbulence modeling has directed its efforts in bringing new initiatives adopted by the heat equation are also valid to introduce motion to further describe kinematic and dynamic conservation of mass, momentum and energy for the thermo dynamical equations which is helpful for the integral formulation of independent variables.

## II. ABOUT BOUNDARY LAYER FLOWS

Structure and circumstances contributes to the changes for a thin shear layer includes phases of solid, liquid and gas matter to derive and coordinate velocity components (u and v) to represent direction velocities (x and y) of motion, inertia and force. The similarity solution for different flows balanced by the forces and torques (moments) of convective inertia to include hypersonic, heat, thermal jets, shallow water equations and blood flows to form an equation with the laminar boundary. This is a very smooth flow where the laminar breaks action and reaction down the transitions as a turbulent flow to coordinate mass, momentum and energy. Ludwig Prandtl on August 12, 1904 divide the flow field into two areas with a phenomena of viscosity with differentiation to coordinate conservation and momentum to balance all the forces and torques (moments) with Navier stokes equations to solve pressure distribution throughout the boundary layer. This describe interactive atmosphere for simulator with properties, pressure, temperature, density of air with atmosphere to appear as a viscous flow for the derivation of the displacement thickness. This simulator helps to develop a mass with two inviscid flows where the no-slip condition assumed to be constant. Here, the displacement thickness is formulated in an Ekman layer forms with all the thermal boundary layer governed by the Prandtl number. It is assumed that the controlling behavior for hypersonic and heat flows helps to minimize drag for motion locally with wall shear stress as a function and to add to the effective thickness to create a skin friction drag. As high Reynolds numbers are less stable as the flow develops also places all the transition process as a prerequisites for thermal jets, shallow water equations and blood flows, for objects with small curvature. These equations can be used with x coordinate (stream wise) and y (normal component) to estimate outside the similarity solution to provide results for inertia and force.

## III. REVIEW ON ROLE OF REYNOLDS NUMBERS IN BOUNDARY LAYER THEORY

S. Goldstein (1969) view for the Navier–Stokes equation heat transfer includes material and transfer properties for the two dimensional equation in the conservative form of  $q_t + F_x + G_y = 0$ . This will describe 99% boundary layer thickness  $\delta$ , the displacement thickness  $\delta^2$  and the momentum thickness  $\theta$  or  $\delta_2$  in a fluid stream where no slip conditions with a common approximation of a fluid slip

coordinate normal and slip length to approximate mean free path. *T. Cebeci & J. Cousteix (1999)* on Reynolds numbers examine the variation of heat flux and scaling laws of a viscous fluid where density  $\rho$ , temperature  $T_\infty$  and a constant velocity  $U_\infty$  and a hot fluid temperature  $T_f$  in the three dimensional boundary layer approximation also includes temperature difference between the fluid and solid with the density of  $q = [\rho, \rho u, \rho v, e]^T$ . With  $x$  and  $y$  are the directional momentum and energy with  $e = \frac{p}{\gamma-1} + \frac{1}{2}\rho(u^2 + v^2)$  will helps to move in the direction to the normal vector with the displacement thickness  $\delta^2$  hypothesis to experiment all the marginal stability approaches of motion and heat transfer in  $\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0$  where  $u, v$  are the velocity components along with  $x$  and  $y$  coordinates with  $T$  as a temperature of a fluid for boundary values and initial data. The continuity and momentum equation for the transformation of the exact solutions, principles and conditions in the *S. Goldstein (1969)* heat transfer the flow properties with  $\rho$  and  $\gamma$  is the specific heat ratio will moved parallel with the momentum thickness  $\theta$  or  $\delta_2$  of the inviscid fluid stream. However, all the velocity describe approximate behavior to move to the normal vector is affected by studies of recirculation flows and flux to balance the power law in relation between the shear stress and the shear rate by  $\tau_{xy} = K \left| \frac{\partial u}{\partial y} \right|^{n-1} \frac{\partial u}{\partial y}$ . All the similar solutions for the simple spinning flow helps in the series expansion to finite difference procedure with the cross flow methods of *S. Goldstein (1969)* to solve the conjugate heat transfer  $F = F^I - F^V$  and  $G = G^I - G^V$  where  $I$  is the inviscid flux part and  $V$  is the viscous part to describe approximate behavior with 99% boundary layer thickness  $\delta$ . This will move with the displacement thickness  $\delta^2$  of velocity where *T. Cebeci & J. Cousteix (1999)* methods of forcing mechanism where  $n = \text{power law index}$ ,  $n < 1$  for pseudoplastic,  $n = 1$  for Newtonian and  $n > 1$  for dilatent fluid in  $u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \frac{\partial}{\partial y} \left( \gamma \left| \frac{\partial u}{\partial y} \right|^{n-1} \frac{\partial u}{\partial y} \right)$  is applicable to all the boundary conditions on a plate surface of  $y = 0, u(x, 0) = 0$  and  $v(x, 0) = 0$ . The affect of vorticity in the three dimensional boundary layer within the lines and the skin friction in the symmetric singular points of *S. Goldstein (1969)* equation includes multi block codes needed for flux vectors to include  $F^I = [\rho u, \rho + \rho u^2, \rho uv, u(p + e)]^T$ ,  $G^I = [\rho v, \rho uv + \rho v^2, \rho v^2, v(p + e)]^T$ ,  $F^V = [0, T_{xx}, T_{xy}, u\tau_{xx} + u\tau_{xy} + kT_x]^T$  and  $G^V = [0, T_{xx}, T_{yy}, u\tau_{yx} + u\tau_{yy} + kT_x]^T$  with the temperature  $T$  and the thermal conductivity coefficient  $k$  describe approximate behavior with 99% boundary layer thickness  $\delta$  to move in the direction perpendicular to the normal vector. Here, with the displacement thickness  $\delta^2$  will move parallel with the momentum thickness  $\theta$  or  $\delta_2$  in an inviscid fluid stream of velocity of *T. Cebeci & J. Cousteix (1999)* on Reynolds numbers always response to the flow characterization with  $-k \frac{\partial T}{\partial y} = h_f(T_f - T_w)$  where  $h_f$  is the heat transfer coefficient,  $k$  is the thermal conductivity to match  $y \rightarrow \infty$

with a free stream for  $u(x, \infty) = U_\infty$  and  $T(x, \infty) = T_\infty$  with an angle of the attaching a separate streamline with various nodes and saddles on a closed and simply connected body. *S. Goldstein (1969)* on heat transfer is compressible and can be implement with the multi block codes and the stress tensors  $\tau_{xx} = 2\mu \frac{\partial u}{\partial x} + \lambda \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right), \tau_{yy} = 2\mu \frac{\partial v}{\partial y} + \lambda \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right), \tau_{xy} = \tau_{yx} = \mu \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right)$  where  $\mu$  and  $\lambda$  are the dynamic and second viscosity helps to describe all the approximate behavior with 99% boundary layer thickness  $\delta$ . Normal vector with the displacement thickness  $\delta^2$  helps to move parallel with the momentum thickness  $\theta$  or  $\delta_2$  in *T. Cebeci & J. Cousteix (1999)* different approach where all the single vortex forcing  $T_w$  as a uniform temperature over the surface plate with a relation  $T_f > T_w > T_\infty$ . By introducing dimensionless variables as  $\psi = bx^{-a}f(\eta)$  and  $\eta = a \frac{y}{x^\beta}$  for  $a, b, \alpha$  and  $\beta$  with  $\psi$  as a stream function of  $u = \frac{\partial \psi}{\partial y}$  and  $v = \frac{\partial \psi}{\partial x}$  in the separation lines will influence momentum integral methods with compressibility and sterility of the three dimensional boundary layers will derive estimates for the distribution of ideal gas law  $p = \rho RT$ . This will describe approximate behavior of 99% boundary layer thickness  $\delta$  in the direction perpendicular to the normal vector with the displacement thickness  $\delta^2$  and move parallel with the momentum thickness  $\theta$  or  $\delta_2$  in an inviscid fluid stream of velocity. This helps to experiments a balance between advective and diffusive heat flux and define with to get  $Pr = \frac{\gamma}{\Theta}$  is the Prandtl number for the non dimensional temperature in the transformed energy equation. However, all the transformed boundary conditions with the transition to turbulence time average boundary layer and momentum integral equations to fluctuate with the integrals of *S. Goldstein (1969)* of Navier Stokes equation. This heat transfer includes numerical simulations with the specific gas constant  $R = c_p - c_v$  to describe approximate behavior and move to the normal vector of stream velocity. *T. Cebeci & J. Cousteix (1999)* balances includes all the fundamental importance of marginal stability in the heat transfer coefficient  $h_f = cx^{-1/(n+1)}$  and provide a similarity solutions with  $h_f$  in proportional to  $x^{-1/2}$  where a uniform surface temperature  $\Theta(0) = 1$  is a form a new boundary condition with  $\Theta(\infty) = \lim_{\eta \rightarrow \infty} \Theta(\eta) = 0$ . *S. Goldstein (1969)* assume all the convective terms and viscous stresses as zero where  $u = v = 0$  to reduce  $\rho_t = 0, \rho_x = 0$  and  $\rho_y = 0$  similar to the variable coefficient of heat equation and describe approximate behavior of layer thickness  $\delta$  affected by external forcing of *T. Cebeci & J. Cousteix (1999)* for all the soft and hard turbulence support.

#### IV. DEVELOPMENT OF THE RESEARCH QUESTION Questionnaire 1

How Boundary theory of Color Clarity Gravity pH Protein Glucose Nitrites Red blood and White blood cell develop all the physical, chemical, and microscopic examination with the Momentum thickness with the two and three dimension Fluid Dynamics and Magneto hydrodynamics (MHD) model

of blood flow?

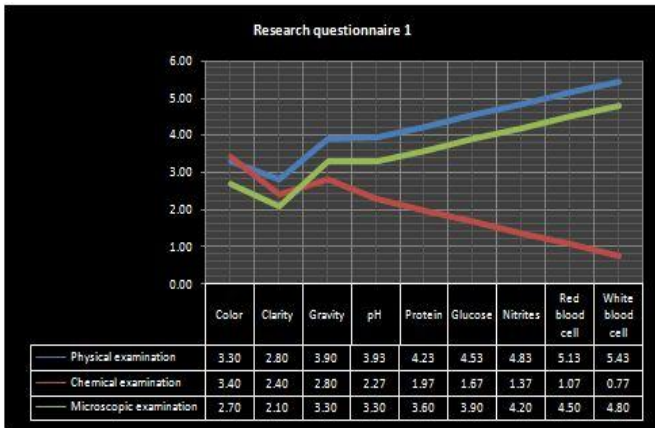

Figure 1: Research questionnaire 1

Questionnaire 2

In a planned and structured process, do Boundary theory identified any special effect with the theory of hemoglobin, cells, platelets, intake, and chronic illness with the dimension of Parasites, Viruses and Bacteria examination of Fluid Dynamics to center fixed and random effects model of blood flow.

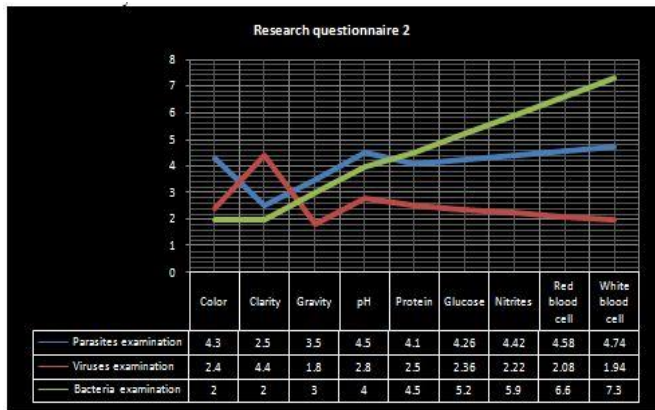

Figure 2: Research questionnaire 2

Questionnaire 3

Acquiring viscous forces in determining the atomic and molecular structure with Navier Stokes equations desire factors affecting Hemoglobin, Cell destruction, Chronic illness, Platelets and Cells of boundary layers in adverse pressure object. Do Boundary theories in all the Fluid Dynamics of blood flow agree with the notion of Influencing parameters?

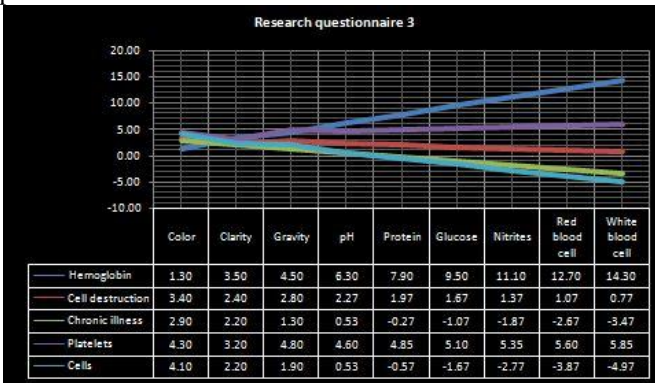

Figure 3 : Research questionnaire 3

Questionnaire 4

Do boundary theory developments may include cardiovascular examination with heart chambers, valves, and vessels for the diagnosis of disorders affecting area with Plasma serum, Bodily fluids and other immune deficiencies. How to agree that this will be helpful in evaluating with the role of shape factors in determining flow pulses to assess fixed and random effects model of blood flow in all dimension?

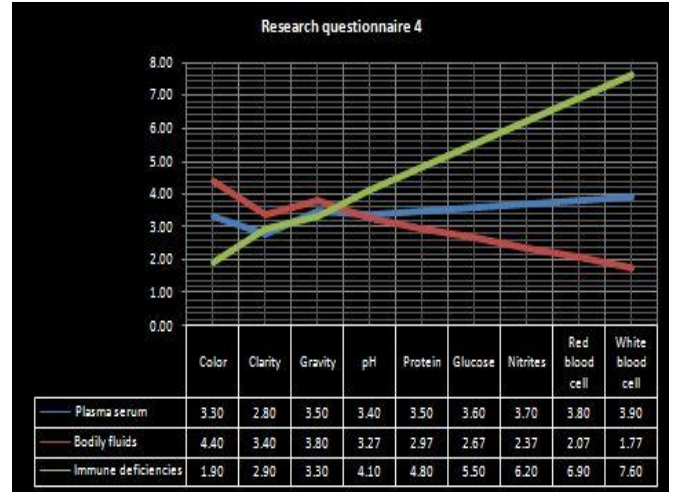

Figure 4: Research questionnaire 4

Questionnaire 5

Do the need for better TMT has given rise to the quality Boundary theory of Color Clarity Gravity pH Protein Glucose Nitrites Red blood and White blood cell development for the Atomic and Molecular structure. Here, how this aims to measure heart's ability in a controlled structured environment observe in all the abnormal blood flow efficiently?

Figure 5: Research questionnaire 5

Questionnaire 6

How to agree to the need of a structured TMT Boundary theory program to pertain and monitor various arterial pressure activities with the Managerial Implications of Boundary layer theory in Fluid dynamics and Magneto hydrodynamics (MHD) cardiomyopathy of blood flow ?

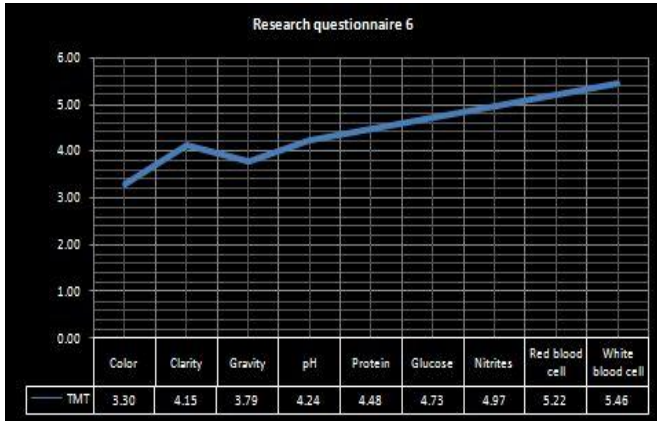

Figure 6: Research questionnaire 6

Questionnaire 7

Does all the Boundary theory use Blood flow velocities for two and three dimensional fluid dynamics in measuring research limitations and recommendations for blood flow velocities to give good information.

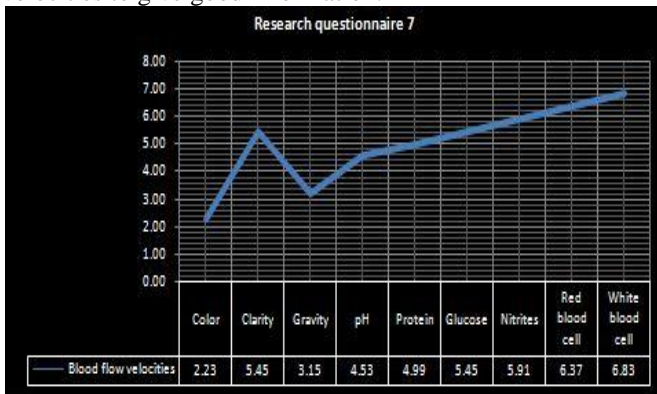

Figure 7: Research questionnaire 7

Questionnaire 8

Coronary artery bypass is the most common type of heart surgery that requires factors affecting boundary layers with a shear stress. Do in different orders how to agree that this is applicable also for TMR (Tran myocardial Laser Revascularization), Heart Valve Repair and Replacement, Arrhythmia Treatment, Aneurysm Repair, and other Surgical Approach with the Fluid Dynamics Effect of Boundary layer theory in all the two and three dimensional blood flow?

Figure 8: Research questionnaire 8

Questionnaire 9

Do implementation of Boundary theory is helpful for patients of coronary artery disease, angina and Bypass suitable for balloon bypass. How to agree that the result with an effective research structure boundary theory of two and three dimensional fluid dynamics of fixed and random effects model for blood flow?

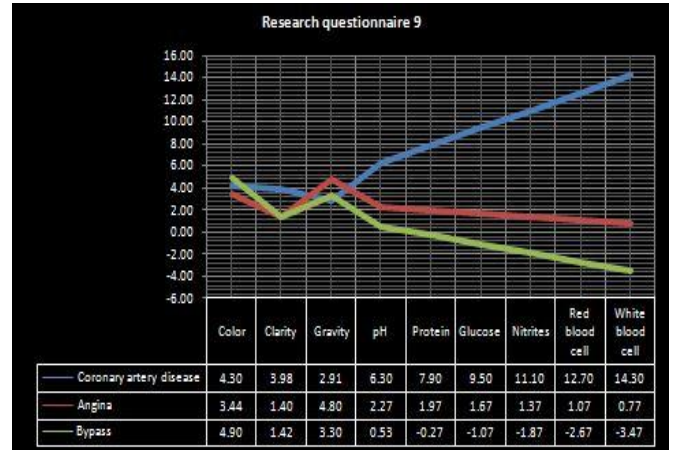

Figure 9: Research questionnaire 9

Questionnaire 10

Does patient's procedure with Reynolds numbers is effective for First order, Second order and Infinite order PDE in Boundary layer theory as an effective research structure to reduce and improve the quality of fixed and random effects model of blood flow?

Figure 10: Research questionnaire 10

V. CONCLUSION

This paper discuss research questionnaire showing the effect of boundary layer theory on aerodynamics, hydrodynamics, transportation, wind and ocean engineering and led to the development of various approximations, equations and comments techniques with critical and with a high failure rate. To describe the requirements for its success use of laminar boundary layer helps to realize with high priority and study the testing of various Laminar flow techniques with an application of Reynolds decomposition for modeling is found to be helpful to examine the relevance of all the PDE testing techniques and suggests the positive associations for different requirements to implement..
