Abstract: Compare to other renewable energy sources solar and wind energy sources are the fastest-growing type of renewable energy sources. While we consider the wind power for electricity generation constant power generation is very necessary for any grid connection in the power system. The integration of wind farms with the power grid leads to Power Quality (PQ) issues such as voltage sag, swell, flicker, harmonics, etc. Most of the industrial and commercial loads are of non-linear type which indeed the starting place of harmonics. As 70% of PQ problems are voltage sag which is one of the most severe disturbances to sensitive loads. As an outcome of the aforementioned issues, both consumer sector and the production sector gets affected with poor quality of power which urges PQ enhancement at its best level. Among many of custom power devices, Unified Power Quality Conditioner (UPQC) is the only device used to diminish both voltage sag and current harmonics. This project analyzes PQ problems, voltage sag and current harmonics due to the interconnection of grid-connected wind turbines and also provides PQ enhancement by introducing UPQC. To improve the performance of UPQC, a novel control strategy using Fuzzy Logic Controller (FLC) is proposed which eliminates the drawback of using fixed gains in conventional PI controller. The simulation of proposed system of Wind power plant connected with grid using UPQC has been carried out in Matlab-Simulink.

Keywords—UPQC, PQ, PI, FLC, WindFarm, etc.

1. INTRODUCTION

A rapid development of wind power generation has been seen in a global scale. As with increasing the size of wind turbines and wind farms, a large amount of wind power is injected to the power system. Due to random nature of wind energy a huge penetration of power may cause important problems and affect the characteristics of the wind generators. The consolidation of wind energy into present existing power system creates technical challenges, which require consideration of stability, voltage regulation related power quality problems. The power quality problems can be seen in accordance to wind generation, transmission and distribution system, such as voltage sag, flickers, voltage swells, harmonics etc. Due to change in voltage, flicker and harmonics failure of devices like microprocessor-based controller, programmable logic controller (PLC), variable speed drives, light source flickering and screen occurs [1]. It also may cause to tripping of contactor, failure of protection device, sensitive equipments stoppage like computers, programmable logic control (PLC) system and may halt the process or even may damage of some sensitive equipments. In transmission and distribution system power quality of supply is very importance measure to be considered. So, considering in wind generation system this power quality issues become so much important measure. As the technology developing in the power generation field the wind power generation developing very quickly. To reduce the disturbances produced by variation in wind flow [2], we use induction generator and connect it directly to the grid system. This induction generator is simple and robust in construction and having reactive power for excitation. However, in induction generators to produce magnetization the reactive power support is required. The major drawback in induction generators is active, reactive power and the terminal voltage varies due to fluctuating wind. A sophisticated control scheme requires in wind generation system when operating normally making proper control of active power production. The new technology in wind generation system use UPQC based control scheme for improvement of the quality of power. Additionally, the wind flow is unpredictable in nature so if there is some disturbance occurs the battery energy storage system (BESS) mitigate the fluctuation of power into the system.

As an outcome of the aforementioned issues, both consumer sector and the production sector gets affected with poor quality of power which urges PQ enhancement at its best level. Among many of custom power devices, Unified Power Quality Conditioner (UPQC) is the only device used to diminish both voltage sag and current harmonics. This project analyzes PQ problems, voltage sag and current harmonics due to the interconnection of grid-connected wind turbines and also provides PQ enhancement by introducing UPQC. To improve the performance of UPQC, a novel control strategy using Fuzzy Logic Controller (FLC) is proposed which eliminates the drawback of using fixed gains in conventional PI controller. The simulation of proposed system of Wind power plant connected with grid using UPQC has been carried out in Matlab-Simulink.

The major drawbacks of any FACTS device with energy storage system(ESS) is that the size of storage system, likely battery energy storage system(BESS), may become too large and bulky for practical large-scale transmission applications. The other problem with battery system is that if numbers of cells are connected in series it results in voltage instability. But on other side if storage system is used then a large oscillation can be minimize only by injecting a small amount of power. So as the combination of a UPQC and BESS
becomes an ideal controller for many types of power quality issues like voltage fluctuation, oscillation damping etc. Also, it has capability of controlling active, reactive power production independently so that it is best suited for stabilization of any kind of power disturbances occurs in power system.

II. PROBLEM IDENTIFICATION AND OBJECTIVES
The power system liberation, along with generation shortage and transmission restriction, has modified the grid conditions by providing space for energy storage devices and its new developed technology performing very important role in bettering power quality and system reliability. The benefits of such storing devices are that it can damp oscillations rapidly, reduces sudden load transients and maintain continuity of supply while a load interruption occurs in transmission or distribution system. The small size energy storing device used in wind generation system can give rated power for very short duration of time and would capable to reduce short term voltage disturbance and so improving power quality. But if there is larger energy reserve connected with wind farm then it can give power certain amount of power for longer duration of time. This increases the availability of power form wind farm and allows shutdowns for smaller stand by units at peak load time. By some means if the size of energy reserve can increase then it allows to make standby some of larger power plants which justify the investment on the whole system.

The integration of wind farms with power grid leads to Power Quality (PQ) issues such as voltage sag, swell, flicker, harmonics etc. Most of the industrial and commercial loads are of non-linear type which indeed the starting place of harmonics. As 70% of PQ problems are voltage sag which is one of the most severe disturbances to sensitive loads. As an outcome of the aforementioned issues both consumer sector and production sector gets affected with poor quality of power which urge PQ enhancement at its best level. Among many of custom power devices, Unified Power Quality Conditioner (UPQC) is the only device used to diminish both voltage sag and current harmonics. This project analyzes PQ problems, voltage sag and current harmonics due to the interconnection of grid connected wind turbine and also provides PQ enhancement by introducing UPQC. To improve the performance of UPQC, a novel control strategy using Fuzzy Logic Controller (FLC) is proposed which eliminates the drawback of using fixed gains in conventional PI controller.

III. OVERVIEW OF CONTROLLING
In this work the performance of UPQC is enhanced by developing a novel control strategy using FLC. The benefits of FLC over the conventional controller are that FLC even works without a perfect mathematical model. Also FLC is capable of handling nonlinearity and is more robust compared to conventional PI controller which also improves the performance of UPQC. The control strategy used in this work is described below.

A. Conventional PI Control strategy
In this control strategy, both shunt and series APF in UPQC is controlled with conventional PI controller as shown in fig.1. And fig.2. The gain values P and I are chosen as Kp=0.1 and Ki=2 using trial and error method. In series APF, the faulted sag voltage is compared with the reference voltage. The error voltage is processed through PI controller and its output is converted to three phase through unit vector generation, then it is fed into Pulse Width Modulation (PWM) generator to provide gate pulses to Series APF such that this can be able to inject the required voltage for the mitigation of voltage sag.

B. Fuzzy Logic Controller
FLC is one of the most successful operations of fuzzy set theory. Its chief aspects are the exploitation of linguistic variables rather than numerical variables. FL control technique relies on human potential to figure out the systems behaviour and is constructed on quality control rules. FL affords a simple way to arrive at a definite conclusion based upon blurred, ambiguous, imprecise, noisy, or missing input data. The basic structure of an FLC is represented in Fig.3.
• A Fuzzification interface alters input data into suitable linguistic values.
• A Knowledge Base which comprises of a data base along with the essential linguistic definitions and control rule set.
• A Decision Making Logic which collects the fuzzy control action from the information of the control rules and the linguistic variable descriptions.
• A Defuzzification interface which surrenders a non-fuzzy control action from an inferred fuzzy control action.

In this project, an advanced control strategy, FLC is implemented along with UPQC for voltage correction through Series APF and for current regulation through Shunt APF. Error and Change in Error are the inputs and Duty cycle is the output to the Fuzzy Logic Controller as shown in Fig. 4-Fig.5.

IV. SIMULATION AND RESULT DISCUSSION
In the below section the UPQC device has been integrated with proposed wind power plant and DFIG system and the voltage profile improvement and the power control also shown in the simulation results.

V. CONCLUSION

Also, one major part of this thesis work is excess power of wind generation can store using high capacity batteries so that the power exchange with grid can be constant and the energy can be utilizing during pike load time. This gives power saving of base load plant and provide a non-polluting power time to time. Thus, the concept is another step in the field of non-polluting energy and reduction in carbon footprint. UPQC integration with DFIG provides power quality improvement with ESS system. The Matlab simulation shows the effectiveness of UPQC for PQ problems mitigation in DFIG wind power plant. The fuzzy controlled UPQC is implemented for PQ enhancement to diminish both voltage sag and current harmonics and the simulation results are also compared with conventional PI controller. From the simulation results, the PI controlled UPQC completely mitigates voltage sag but the load current harmonics obtained is not within the acceptable bounds. Thus the proposed Fuzzy controlled UPQC is successfully proven as efficient device through its outstanding performance for improving PQ in a grid connected wind power system.
