Abstract: Production and Inventory are the pillars for the success of the industry. For the proper functioning of the industry, proper production control and scheduling is important and together with that the proper inventory management is also necessary to avoid the wastage and over stock age of raw materials. This paper reviews the production planning and inventory management.

1. INTRODUCTION

Production planning is the demonstration of building up a guide for the plan and production of a given item or administration. Production planning assists associations with making the production process as proficient as could really be expected. Production planning began to improve the assembling process, and today its overall rationale is applied in different structures to plan, production and conveyance of programming also. [1]

Production planning is significant on the grounds that it makes an effective process for production as per client and authoritative requirements. It advances both client subordinate processes - , for example, on-time conveyance - and client autonomous processes, for example, production process duration. [1]

A decent production plan limits lead time, which is the measure of time that passes between the putting in of a request and the finish and conveyance of that request. Contingent upon the organization and the sort of production planning fundamental, the meaning of lead time changes marginally. In production network the executives, for instance, lead time incorporates the measure of time it takes for parts to transport from a provider. This is incorporated in light of the fact that the assembling business has to know when the parts will show up to appropriately execute material necessities planning (MRP). This is particularly significant with tight assembling requirements or without a moment to spare (JIT) producing. [1]

2. PRODUCTION PLANNING PROCESS

The production planning process includes the accompanying advances:

Gauge item interest - This will a give a harsh diagram of the number of items ought to be created in a given time-frame.

This gauge is created by consolidating examination of chronicled production patterns with new conceivable pertinent patterns on the lookout. [2]

Gauge production choices - This includes representing the assets available and investigating approaches to most successfully utilize them dependent on projected interest gauges.

Pick the most effective alternative - The utilization of assets that is the most un-exorbitant and most time-productive ought to be picked. [2]

Checking and assessment - As the arrangement is completed, organizations screen what’s going on contrasted with what ought to occur as per the arrangement, and assess how well those two coordinate. [2]

Change plan - This includes modifying the arrangement so future production plans meet client objectives all the more productively and are more fruitful in their execution.

3. SORTS OF PRODUCTION PLANNING

There are numerous sorts of production planning that attention on different specifics of the production process. A portion of these include: [3]

Expert production plan (MPS) - These are plans for singular, explicit items to be created in a given time-frame. They are frequently produced by programming, and afterward changed by clients. [3]

Material necessities planning - MRP is a framework utilized for production planning, booking and stock control. MRP guarantees the accessibility of crude materials, keeps up the most reduced conceivable material and item levels in-house, and plans assembling and buying exercises. It is regularly computerized somewhat by programming, yet can be performed totally physically too. [4]

Scope quantification - This is the process of figuring out what limit an association needs to fulfill evolving needs. [4]

Work process planning - This is the planning of a succession of tasks performed by a worker or gathering of representatives.

There are additionally different planning types that apply the rationale of production planning to zones other than assembling, or correlative regions. For instance, HR planning...
includes improving processes that permit an organization to meet their employing and ability requests. Different models include:

**Venture asset planning (ERP)** - This is the combination of principle business processes into one bound together framework, regularly using programming.

**Deals and tasks planning (S&OP)** - This is the process for all the more precisely coordinating with a producer's stock with existing interest.

**Production booking**

Production booking resembles production control. Production planning is the allotment of accessible assets to production processes and occasions. It is basically the planning of real assets to the production plan worked for them. Booking is utilized to design utilization of plant gear and assets, and to design processes and material buying. Booking is important to make a production plan. Production plans expect to at last follow through on client interest. The objective of a production plan is to make the most proficient production plan conceivable. [4]

### 4. HISTORY OF PRODUCTION PLANNING

Present day production planning has its foundations in the main portion of the nineteenth century. It created out of a requirement for data around inner planning in control. Elements like railways, material plants and different industrial facilities required inner regulatory systems to direct the various processes associated with giving their fundamental item or administration at a huge scope. [5]

The principal production plans were straightforward. Plants were generally little and created a set number of items in huge group sizes. Industrial facility foremen were specialized specialists in their field, and dealt with all planning and booking, which here and there would incorporate close to a rundown of production orders and the date at which they were to be finished. [5]

As the production line and assembling endeavors overall increased and more mind boggling, more elaborate production planning was important. By the start of the twentieth century, plans started zeroing in on conveying orders, however enhancing the processes needed to do as such, so production process stream could be just about as even as conceivable at the base conceivable production cost.

Today, as the idea of production strategies and assembling has changed, so has production planning. The innovation encompassing production has developed, empowering more exact correspondence and checking of and around production. The actual items, and client assumptions, have likewise developed. Presently, there is more data accessible than any other time for associations to weigh while making their production plans. [5]

### 5. INVENTORY MANAGEMENT

Inventory changes continually. Consistently, deals, returns, new receipts – even harm and robbery – influence your inventory levels. While overwhelming, powerful inventory management and inventory control are the main positions in an effective retail or discount business.
