CONTROLLING OF BIDIRECTIONAL DC-DC CONVERTERS AND AC/DC CONVERTERS FOR SOLAR PV-WIND-BATTERY BASED HYBRID SYSTEM

Abstract— In renewable energy systems, fluctuating outputs from energy sources and variable power demand may deteriorate the voltage quality. In this paper a model predictive control strategy without using any proportional-integral-derivative (PID) regulators is proposed. The proposed strategy consists of a model predictive current and power (MPCP) control scheme and a model predictive voltage and power (MPVP) control method. By controlling the bidirectional dc-dc converter of the battery energy storage system based on the MPCP algorithm, the fluctuating output from the renewable energy sources can be smoothed, while stable dc-bus voltage can be maintained. Meanwhile, the ac/dc interlinking converter is controlled by using the MPVP scheme to ensure stable ac voltage supply and proper power flow between the microgrid and the utility grid. Then, a system-level energy management scheme (EMS) is developed to ensure stable operation under different operation modes by considering fluctuating power generation, variable power demand, battery state of charge (SOC), etc. The Proposed System is simulated using Matlab-Simulink with simulation results analysis.

Keywords—PV, MPVP, MPCP, EMS, PID, SOC, etc.

1. INTRODUCTION

There are many rural villages in countries around the world that do not have access to electricity. According to International Energy Agency (IEA), more than 1.3 billion people around the world do not have access to electricity. Approximately 84% of these people live in rural villages. Recently, because of the advancement in power electronics, renewable energy sources and energy storage technologies have allowed the cost of led the cost of energy from renewable resources to compete with conventional resources. One of the existing solutions to electrify rural villages is the use of MG energy systems.

An MG can be defined as a group of interconnected loads and distributed energy resources within clearly defined electrical boundaries. These resources act as a single controllable entity that connects or disconnects from the grid to enable it to operate in a grid-connected or “island” mode. The hybridization and integration of renewable energy resources for an MG are used to obtain optimal control and energy management. Figure 1.1 shows a block diagram for a MG energy system. Recently, due to the increasing presence of dc power sources in microgrids such as PV, fuel-cell, energy storages, modern dc loads, and considering the existing century-long ac power systems, interests on hybrid ac/dc microgrids are growing rapidly. Traditionally, cascade inner current and outer voltage feedback loop with PID regulators are commonly used to control dc-dc converters and ac/dc interlinking converters in such microgrids. In renewable energy systems, fluctuating outputs from energy sources and variable power demand may deteriorate the voltage quality.

In this paper a model predictive control strategy without using any proportional-integral-derivative (PID) regulators is proposed. The proposed strategy consists of a model predictive current and power (MPCP) control scheme and a model predictive voltage and power (MPVP) control method. By controlling the bidirectional dc-dc converter of the battery energy storage system based on the MPCP algorithm, the fluctuating output from the renewable energy sources can be smoothed, while stable dc-bus voltage can be maintained. Meanwhile, the ac/dc interlinking converter is controlled by using the MPVP scheme to ensure stable ac voltage supply and proper power flow between the microgrid and the utility grid.

2. RESEARCH OBJECTIVES

Over recent years several research and investment has been carried out in hybrid power system who recommended an optimal design model for hybrid solar–wind system, which employs battery banks to calculate the system’s optimum configurations in Power system. The different researchers have presented a hybrid solar-wind system as a renewable source of power generation for grid connected application in any country. They also modeled a hybrid solar wind power plant in different countries two-year period using hourly solar irradiation and wind speed data. The limitations of
global resources of fossil and nuclear fuel, has necessitated an urgent search for alternative sources of energy. Therefore, a new way must be found to balance the supply and demand without resorting to coal and gas fuelled generators.

Integration configurations between different energy sources and loads in an MG can be categorized into three possible configurations: AC coupled, DC coupled, and hybrid coupled configuration as shown in Figure 2.1. Each configuration has its own advantages and disadvantages in terms of control complexity, cost, efficiency and reliability.

Research Problems…
• For decades, cascade linear control has dominated the power electronic control techniques.
• However, this approach has major drawbacks.
  1. First, the control structure is complicated with multiple feedback loops and PWM modulation, which leads to slow dynamic response.
  2. Second, the tuning of the proportional-integral-differential (PID) parameters is time-consuming, which makes the controller not easy to implement.
• In a practical microgrid, fluctuating output from renewable energy sources can cause oscillations in dc-bus voltage, which in turn, may further deteriorate the power quality on the ac side.

Research Objectives

3. PROPOSED WORK
For decades, cascade linear control has dominated the power electronic control techniques. However, this approach has major drawbacks. First, the control structure is complicated with multiple feedback loops and PWM modulation, which leads to slow dynamic response. Second, the tuning of the proportional-integral-differential (PID) parameters is time-consuming, which makes the controller not easy to implement. In a practical microgrid, fluctuating output from renewable energy sources can cause oscillations in dc-bus voltage, which in turn, may further deteriorate the power quality on the ac side. As a result, traditional cascade control may no longer be effective to deal with this fluctuation.
Recently, due to the increasing presence of dc power sources in microgrids such as PV, fuel-cell, energy storages, modern dc loads, and considering the existing century-long ac power systems, interests on hybrid ac/dc microgrids are growing rapidly. Traditionally, cascade inner current and outer voltage feedback loop with PID regulators are commonly used to control dc-dc converters and ac/dc interlinking converters in such microgrids. Typically, in islanded mode, the main ac/dc interlinking converter is controlled to provide a stable voltage and frequency for the ac sub grid while the dc-link voltage is maintained by the bidirectional dc-dc converter. In grid-connected mode, the ac/dc interlinking converter is used to maintain a stable dc-link voltage and to exchange power between the microgrid and the utility system. As the dc-dc converters and the ac/dc interlinking converters are vital to ensure stable dc and ac supply, the drawbacks of the conventional cascade control with PID regulators may affect the voltage quality. Another concern is that, in existing microgrid research, the inputs of the distributed inverters are usually connected to ideal dc power sources to simulate a variety of renewable energy resources. For control techniques development of inverters, it is reasonable and sufficient because this assumption can facilitate the design process. From the viewpoint of practical applications, however, the intermittent nature of such energy resources must be considered. Under variable power generation and power demand conditions, the traditional cascade control methods may no longer be effective to deal with this fluctuation. More advanced control methods may therefore be required to ensure stable operation and high power quality.

In this paper a new control strategy based on MPC is developed for renewable energy based microgrids. The topology of the microgrid is shown in Fig. 3.1. The renewable energy resources could be the wind, solar, wave, etc. Here, solar PV system and wind generator are adopted as an example, which is not the main focus in this research. There are two parts in the whole system: DC sub grid with dc loads and ac sub grid with ac loads. The battery energy storage system (BESS) is connected to the dc bus via a dc/dc converter. The ac and dc buses are interconnected through a bidirectional ac/dc interlinking converter which is a three-phase two-level voltage source inverter (VSI).

A model predictive current and power (MPCP) scheme is developed to control the bidirectional dc-dc converter in the BESS, while a model predictive voltage and power (MPVP) method is proposed to control the ac/dc interlinking converter. They are used to coordinately control the dc/dc converter and ac/dc converter to smooth the renewable energy outputs and maintain dc- and ac-buses voltages. Finally, by considering practical aspects such as fluctuating power generation, variable power demand, battery state of charge (SOC), electricity price, etc., an energy management scheme (EMS) is developed to ensure stable operation under different operation modes. Our contributions in this work are highlighted as follows.

1) Compared with traditional cascade linear control, the proposed scheme avoids PID parameters tuning, PWM modulation and complex coordinate transformation.
2) By using proposed MPC scheme, the dc-bus voltage can be better maintained with less oscillations and overshoots under fluctuating power generation and consumption profiles. Meanwhile, the ac-bus voltage has a better quality with less harmonic interferences.
3) A comprehensive system-level power management scheme in consideration of fluctuating power generation, variable power demand, battery state of charge (SOC), and electricity price is developed to ensure stable operation and steady transition under different operation modes.

The aim of the BESS is to compensate the power gap caused by the renewable energy sources and the load demand. Since the power supplied or absorbed by BESS is actually controlled by switching the buck-boost converter, it is necessary to obtain the effect of its switching states on the power supplied/absorbed.

4. SIMULATION & RESULTS

Fig 4.1- Matlab Simulation of A microgrid with multiples energy sources and converters
In this Paper, a new control strategy based on MPC is developed for renewable energy based microgrids. The topology of the microgrid is shown in Fig. 4.1.

The renewable energy resources could be the wind, solar, wave, etc.

Here, solar PV system and wind generator are adopted as an example, which is not the main focus in this research.

There are two parts in the whole system: DC sub grid with dc loads and ac sub grid with ac loads. The battery energy storage system (BESS) is connected to the dc bus via a dc/dc converter.

The ac and dc buses are interconnected through a bidirectional ac/dc interlinking converter which is a three-phase two-level voltage source inverter (VSI).

A model predictive current and power (MPCP) scheme is developed to control the bidirectional dc-dc converter in the BESS, while a model predictive voltage and power (MPVP) method is proposed to control the ac/dc interlinking converter.

They are used to coordinately control the dc/dc converter and ac/dc converter to smooth the renewable energy outputs and maintain dc- and ac-buses voltages.

This mode refers to grid-connected operation. Any power surplus or deficit within the microgrid is automatically balanced by the ac distribution network. In this case, the PV and wind generator should produce as much power as possible for the microgrid and the utility. Also, no load shedding is required and the ESS can be charged or discharged depending on the actual electricity price.
Simulation Results under Islanded performance under variable PV power and load demand condition

This mode refers to islanded operation. Since the hybrid microgrid becomes an isolated system, the power needs to be balanced within the microgrid. In this case, the dc-bus voltage is maintained by the ESS. The ac-bus voltage is established by the ac/dc interlinking converter using MPVP scheme. Specifically, there are two conditions that need to be considered.

Low wind and irradiation and heavy load

Under this scenario, the generation from PV and wind cannot meet the load demand. As a result, both the PV and wind generator should operate in MPPT while the ESS provides additional power by battery discharging. If the required power by the ESS exceeds the power rating of the battery or the SOC drops down to the minimum value, load shedding becomes necessary to guarantee power supply to the most critical loads.

High wind and irradiation and light load

Under this circumstance, the generation from PV and wind is greater than the load demand. The ESS is used to absorb the excessive energy by charging the battery. If the power absorbed by the battery exceeds the power rating of the battery or the SOC reaches the maximum value, Off-MPPT operation of the PV and wind systems are needed.
Existing research seldom mentions the grid synchronization and connection of the hybrid ac/dc microgrids, which will be studied here. The grid synchronization algorithm starts to operate at 0.25s and the microgrid is connected to utility grid at 1s. It can be seen that the ac terminal voltage of the microgrid is able to track the utility grid voltage in a short time. It is also seen that no major overshoots of currents are observed. These prompts fast and smooth grid synchronization and connection operation.

5. CONCLUSION

In this paper a model predictive control strategy of a microgrid with PV-wind-battery sources is proposed. A model predictive current and power (MPCP) scheme is developed to control the bidirectional dc-dc converter in the battery energy storage system (BESS), while a model predictive voltage and power (MPVP) method is proposed to control the ac/dc interlinking converter. They are used to coordinately control the dc/dc converter and ac/dc converter to smooth the renewable energy outputs and maintain dc- and ac-buses voltages. At the system level, a comprehensive energy management scheme is developed to ensure stable operation under different operation modes. The effectiveness of the proposed method is validated based on a pv-wind-battery system with real-world solar and wind profiles, showing better control capability and improved voltage quality in comparison with traditional method. It should be noted that, compared to traditional cascade control with PID regulators, additional measurements are needed for the proposed MPCP and MPVP approaches.
