ABSTRACT: This research work presents the efficacy of sodium based alkaline activators and class F fly ash as an additive in improving the engineering characteristics of expansive Black cotton soils. Sodium hydroxide concentrations of 10, 12.5 and 15 molar along with 1 Molar solution of sodium silicate were used as activators. The activator to ash ratios was kept between 1 and 2.5 and ash percentages of 20, 30 and 40 %, relatively to the total solids. The effectiveness of this binder is tested by conducting the Unconfined compressive strength (UCS) at curing periods of 3, 7 and 28 days and is compared with that of a common fly ash based binder, also the most effective mixtures were analyzed for mineralogy with XRD. Suitability of alkaline activated fly ash mix as a grouting material is also ascertained by studying the rheological properties of the grout such as, setting time, density and viscosity and is compared with that of common cement grouts.

Keywords: engineering characteristics, Black cotton soils, class F fly ash, Unconfined compressive strength (UCS), alkaline activated, rheological properties.

I. INTRODUCTION

Expansive soils also known as swelling soils or shrink-swell soils are the terms applied to those soils, which have a tendency to swell and shrink with the variation in moisture content. As a result of which significant distress in the soil occurs, causing severe damage to the overlying structure. During monsoon’s, these soils imbibe water, swell, become soft and their capacity to bear water is reduced, while in drier seasons, these soils shrink and become harder due to evaporation of water. These types of soils are generally found in arid and semi-arid regions of the world and are considered as a potential natural hazard, which if not treated well can cause extensive damages to not only the structures built upon them but also can cause loss of human life. Soils containing the clay minerals montomorillonite generally exhibit these properties. The annual cost of damage to the civil engineering structures caused by these soils are estimated to be 15000 million in the India, 100000 million in the U.S. and many billions of dollars worldwide.

Fly Ash

Fly ash is a waste material, which is extracted from the flue gases of a coal fired furnace. These have close resemblance with the volcanic ashes, which were used as hydraulic cements in ancient ages. These volcanic ashes were considered as one of the best pozzolans used till now in the world.

Fly ash Generation and Disposal

For generation of steams, generally coal is used as a fuel in thermal power plants. In the past coal in the forms of lumps were used to generate steam from the furnaces of boilers, but that method proves to be non-energy efficient. Hence to optimize the energy from coal mass, the thermal power plants use pulverized coal mass. Firstly the pulverized coal mass is injected into combustion chamber, where it burns efficiently and instantly. The output ash is known as fly ash, which consists of molten minerals. When the coal ash moves along with the flue gases, the air stream around the molten mass makes the fly ash particle spherical in shape. The economizer is subjected, which recovers the heat from fly ash and stream gases. During this process, the temperature of fly ashes reduced suddenly. If the temperature falls rapidly, the fly ashes are resulting amorphous or glassy material and if the cooling process occurs gradually, the hot fly ashes becomes more crystalline in nature. It shows that the implements of economizer, improves its reactivity process.

Classification of Fly Ash

After Pulverizations, the fuel ash extract from flue gases, by electrostatic precipitator is called fly ash. It is finest particles among Pond ash, Bottom ash and Fly ash. The fly ashes are extracted from, high stack chimney. Fly ash contains non-combustible particulate matter, with some of unburned carbon. Fly ashes are generally contains silt size particles. Based on lime reactivity test, fly ashes are classified in four different types, as follows:

- Cementitious fly ash
- Cementitious and pozzolanic fly ash
- Pozzolanic fly ash
- Non-pozzolanic fly ash

Justification of the Research
In India, almost 20% of the total area is covered by expansive soil, now due to rapid industrialization and huge population growth of our country, there is a scarcity of land, to meet the human needs. And also the cost of rehabilitation and retrofitting of the civil engineering structures founded over these soils are increasing day by day. On the other hand, the safe disposal of fly ash from thermal power industries has been a challenging issue demanding urgent solution because of the decline effect of these materials on the environment and the hazardous risk it pose to the health of humanity. However, production of cement require lime-stone and with the rate with which we are utilising cement, the day is not so far when the lime stone mines will get depleted, and this is a matter of fact that for every 1 kg of cement manufacturing, 1 kg of carbon dioxide is released into the atmosphere, which in turn increases the carbon footprint and also possess serious threat to the global warming. Thus there is a need to find out alternative binder, which is environmental friendly as well as depended like cements. Hence, this research is justifiable in the use of alkali-activated fly ash to stabilize Black Cotton soil.

Objective of thesis
The objective of the current research work is to ascertain the suitability of activated fly ash as a soil stabilizing agent.

II. LITERATURE REVIEW
Stabilization is one of the methods of treating the expansive soils to make them fit for construction. Variety of stabilizers may be divided into three groups (Petry 2002): (a) traditional stabilizers (lime, cement etc.), (b) by-product stabilizers (fly ash, quarry dust, phosphor-gypsum, slag etc.) and (c) non-traditional stabilizers (sulfonated oils, potassium compounds, polymer, enzymes, ammonium chlorides etc.). Disposal of large quantities of industrial by-products as fills on disposal sites adjacent to industries not only requires large space but also create a lot of geo-environmental problems. Attempts are being made by various organizations and researchers to use them in bulk at suitable places. Stabilization of expansive soil is one way of utilization of these by-products. Some of the research work conducted by earlier researchers on the above has been described below.

Sharma et al. (1992) studied stabilization of expansive soil using mixture of fly ash, gypsum and blast furnace slag. They found that fly ash, gypsum and blast furnace slag in the proportion of 6: 12: 18 decreased the swelling pressure of the soil from 248 kN/m2 to 17 kN/m2 and increased the unconfined compressive strength by 300%.

Srivastava et al. (1997) studied the change in micro structure and fabric of expansive soil due to addition of fly ash and lime sludge from SEM photograph and found changes in micro structure and fabric when 16% fly ash and 16% lime sludge were added to expansive soil. Srivastava et al. (1999) have also described the results of experiments carried out to study the consolidation and swelling behaviour of expansive soil stabilized with lime sludge and fly ash and the best stabilizing effect was obtained with 16% of fly ash and 16% of lime sludge. Kokca (2001) used up to 25% of Class-C fly ash (18.98 % of CaO) and the treated specimens were cured for 7 days and 28 days.

The objective of the current research work is to ascertain the suitability of activated fly ash as a soil stabilizing agent.
To get a clear homogeneity, the samples are mixed thoroughly and heated in an oven maintained at 105-110 °C for 24 hours and then is stored in an air tight container, for subsequent use.

**Activator solution**

The alkaline activator solution used was a combination of sodium silicate and sodium hydroxide. The sodium silicate was originally in powder form and is procured Loba Chemie, Thane Maharashtra, having molecular weight of 284.20 gm/mole and specific gravity of 1.5. While the sodium hydroxide was originally in flake form with a molecular weight of 40 gm/mole, and specific gravity of 2.13 at 20º C and 95-99% purity. The sodium hydroxide pellets were procured from Merck specialties Pvt. Ltd. Mumbai, Maharashtra, India.

**Methodology Adopted**

To evaluate the effect of the ash/soil ratio (by dry mass) on mechanical strength, three different fly ash percentages, regarding the total solids (soil + ash) weight, were used: 20, 30 and 40 %, corresponding to ash/soil ratios of 0.25, 0.43 and 0.67, with activator/total solids ratios of 0.15, 0.2 and 0.25. The details of the experimental specimens are shown in Table 3.3. The soil and the ash were previously homogenized before the activator was added to the mixture. After mixing for 3 min, the samples were cast into 50-mm moulds by tapping the moulds on the lab counter, which were then left in a sealed container. Since the behaviour of the mixtures was that of a viscous fluid, no density control was used during the preparation of the samples. However, when removed from the moulds, every sample was weighted, and an average unit weight of 20 kN/m³ was obtained, regardless of the fly ash percentage in the mixture. The 15 molal mixtures showed a very high viscosity which made the preparation and handling process more difficult than with the remaining concentrations, to a point where this factor should be considered when designing future studies and/or applications. This effect is related to the SiO₂ : Na₂O mass ratio of the silicate + hydroxide solution which, for the 15 molar activator, is approximately 1, making the meta silicate solution very unstable and favoring crystallization. This SiO₂:Na₂O mass ratio was, in the original silicate solution, approximately 2, but the addition of the hydroxide solution reduced it significantly, especially in the 15 molar mixtures. After 48 h, the samples were removed from the moulds and wrapped in cling film and left at ambient temperature and humidity conditions (50–60 % RH and 32-35º C). Immediately before testing, at the ages of 3, 7 and 28 days, the samples were trimmed to 100 mm long and tested for unconfined compressive strength (UCS) on an Aimil hydraulic testing machine. Every single result obtained was the average of 3 tested samples.

Setting time was ascertained by using Vicat’s apparatus. Each grout was poured in the mould in the view point of calculating its initial and final setting time.

**IV. RESULT & DISCUSSIONS**

**Results on Stabilization Of Expansive Soils With Fly Ash**

This chapter presents the results of stabilization of expansive black cotton soil, with fly ash. The increase in strength criteria is ascertained by conducting unconfined compression test on samples, at 3, 7 and 28 days curing. The samples, casted were of 50 mm diameter and 100 mm height, thereby ensuring L/D ratio as 2. These samples contains fly ash in 20, 30 and 40% by weight of dry mass and water to total solid ratio is varied from 15, 20 and 25%. All the samples were covered with cling film, after casting and are kept in a air tight container for 48 hours. After 48 h, the samples were removed from the moulds and wrapped in cling film and left at ambient temperature and humidity conditions (50–60 % RH and 32-35º C). Immediately before testing, at the ages of 3, 7 and 28 days, the samples were trimmed to 100 mm long and tested for unconfined compressive strength (UCS) on an Aimil hydraulic testing machine at constant strain rate of 1.2 mm/min. Every single result obtained was the average of 3 tested samples.

Figure - UCS results of F-15-20, F-15-30, F-15-40

It is evident from the Table 4.1, that the mix F-15-20, is giving more strength at 3, 7 and 28 days than the other two. The 3 day strength of F-15-20 is 6% more than that of F-15-30 and 27% more than that of F-15-40. Similarly the 7 day strength of F-15-20 is 29% more than that of F-15-30 and is about 96% more than that of F-15-40. Moreover the 28 day strength of mix F-15-20 is nearly 30% more than that of F-15-30 and is 43% more than that of F-15-40. The variations of strength of the mixes are shown in Figure 4.2, and it can be stated as the strength of the mix is directly proportional to the curing period and is inversely proportional to the fly ash content in the mix. Thus it can be concluded that for a constant water to total solid ratio, the strength increases with the curing period and also with the decreased fly ash content.

V. CONCLUSIONS

Based on the obtained results and discussion thereof following conclusions can be made.
- The unconfined compressive strength soil is found to vary with concentration of chemical in the activated fly ash and curing period.

- 10 molal samples are giving better 3 and 7 days strengths than 12.5 and 15 molal samples, which make it economical as compared to 12.5 and 15 molal samples.

- Long term strength is more in case of 12.5 molal samples.

- Maximum 3 day strength attained by activated sample is 392.7 kPa, which is 3.25 times more than that attained by fly ash treated samples.

- Maximum 7 day strength attained by activated sample is 546.88 kPa, which is 2 times more than that attained by fly ash treated samples.

- Maximum 28 day strength attained by activated sample is 977.09 kPa, which is 2.7 times more than that attained by fly ash treated samples.

- There is a strong dependency between the activator/ash ratio and mechanical strength.

Results showed that it is advantageous to reduce this ratio since it has a positive effect on strength results, which has also a positive effect on final cost.

- Lowering the viscosity of the grout mixtures to similar values to that of cement grout can have a negative effect on final strength, since it demands an increase in the activator/ash ratio. Therefore, it is recommended that a compromise is made between an optimum viscosity level and the lowest activator/ash ratio possible, whenever the viscosity is a key issue for a particular application.

- Alkali-activated fly ash can be used effectively as a chemical stabiliser for stabilising expansive soils.
