**Abstract:** The image noise cancellation is an interesting field in research due to the dynamic nature of images in special domain. Several approaches has been identified in adaptive filter which is extension of RLMS filter is one of them to achieve higher signal to noise ratio. In this paper, an adaptive filter with two dimensional block processing for color image noise abolition is proposed. Simulations for different block size (2x2, 4x4, 16x16 and 32x32) are performed to signify the approach. The simulation results show that approach performs well.

**Keywords:** adaptive algorithm, block processing, least mean square approximation, noise abolition and PSNR.

## I. INTRODUCTION

Image noise is random variation of brightness or colour information in images, and is usually a type of electronic noise. It can be produced by the sensor and circuitry of a scanner or digital camera. Image noise is an undesirable by-product of image capture that adds spurious and extraneous information.

Main types of noises are Gaussian noise ,Salt and paper noise ,Shot noise

Quantization noise: The noise caused by quantizing the pixels of a sensed image to a number of discrete levels is known as quantization noise. Adaptive filters are widely used in various applications for achieving a better performance

An adaptive filter is a filter that self-adjusts its transfer function according to an optimization algorithm driven by an error signal the dimension of the adaptive filters varies from application to application. In the fields of digital signal processing and communication echo cancellation, noise canceling, and channel equalization [2]-[6], the one-dimensional adaptive algorithm are generally adopted.

Adaptive algorithms are usually classified into two families. One is the least-mean-square (LMS) family; the other is the recursive-least-square (RLS) family. The algorithms in the LMS family have the characteristics of easy implementation and low computational complexity [1]. In the applications of digital image processing, two- dimensional (2-D) adaptive algorithms such as TDLMS, TD- BLMS, OBA, OBAI, and TDOBSG are usually used [9]- [12]. Either in TDLMS or TDBLMS, the convergence factors are remains intact. While in TDLMS and TDBLMS, the space-varying convergence factors are used for better convergence performance. However, such space-varying convergence factors will increase the computational complexity due to the computations for the new convergence factor each time for next block In this paper we proposed weight training mechanism for adaptive filter used for color mage that will process three colours i.e. red, green and blue individually

## II. 2D BLOCK RLMS ALGORITHM

2-D signal is partitioned into blocks with a dimension of  $L \times L$  for each in the 2-D disjoint block-by-block image processing. An image with  $R$  rows of pixel and  $C$  columns of pixel partitioned into  $\frac{R}{L} \times \frac{C}{L}$  blocks is illustrated in Fig. 1. The block index  $S$  and the spatial block index  $(r, c)$  is related by [12]

$$s = (r - 1) \cdot \left(\frac{c}{L}\right) + c \quad (1)$$

Where  $r = 1, 2, \dots, R/L$  and  $c = 1, 2, \dots, C/L$ .

for convenience, the  $(r, c)$ -th element  $d(r, c)$  of the image can be treated as the  $(r_b, c_b)$ -th element in the  $S$ -th block and denoted as the element  $d_s(r_b, c_b)$

The relationship is

$$d_s(r_b, c_b) + d[(r - 1)L + r_b, (c - 1)L + c_b] \quad (2)$$

where  $r_b = 1, 2, \dots, L$  and  $c_b = 1, 2, \dots, L$

Fig-1 2D block by block processing with disjoint square block of dimension  $L \times L$

The block processing is started by processing the image block-by-block sequentially from left to right and from top to bottom in which each pixel is convolved the pixel in a filter window with a dimension of  $M \times N$ . Fig. 2 illustrates this approach which performs the operations from (3) to (5) iteratively [10]. That is,

$$y_s(r_b, c_b) = \sum_{i=1}^M \sum_{j=1}^N W_s(i, j) \times X_s(r_b, c_b) \quad (3)$$

$$= \sum_{i=1}^{M-1} \sum_{j=1}^{N-1} W_s(i, j) \times X_s[(r - 1)L + r_b + M - 1 - i, c - 1L + c_b + N - 1 - j]$$

where  $y_s(r_b, c_b)$  is the image of the  $S$ -th block after processing,  $W_s(i, j)$  is the  $(i, j)$ -th element in the weight matrix  $W$  of the  $S$ -th block. The error signal  $e_s(r_b, c_b)$  is then obtained by subtracting the image  $y_s(r_b, c_b)$  from the primary input image  $d_s(r_b, c_b)$ .

$$e_s(r_b, c_b) = d_s(r_b, c_b) - y_s(r_b, c_b) \quad (4)$$

the weight matrix  $W_{s+1}$  of (S+1)- th block is then updated by

$$W_{s+1}(i, j) = W_s(i, j) + \frac{2}{L^2} \mu \sum_{r_b=1}^L \sum_{c_b=1}^L e_s(r_b, c_b) \times X_s(r_b + rL - i, c_b + cL - j) \quad (5)$$

Where  $\mu$  is convergence factor

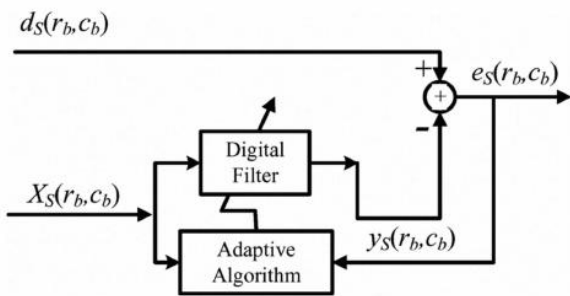

Fig-2 D adaptive filter for image noise cancellation

### III. ADAPTIVE FILTER WITH WEIGHT TRAINING AND ADAPTION

#### 3.1 Weight training phase

To enhance the convergence rate, a suitable weight matrix  $W_{T_a}$  will be treated as the initial weight matrix and  $W_1$  for the the processing in the block-adaption phase is found in the weight-training phase. In weight training phase, all the elements of the initial weight matrix  $W_{T_1}$  are set to be zero. That is,  $W_{T_1} = [W_{T_1}(i, j)]_{M \times N}$  where  $W_{T_1}(i, j) = 0$  for  $i = 1, 2, \dots, M$  and  $j = 1, 2, \dots, N$ . Then, the 2D block RLMS algorithm is applied to process the original noisy image that will be scanned block-by-block from left to right and from top to down for updating the weight matrix of each block iteratively until the termination criterion is reached [10]. Fig. 3 illustrates this approach, the termination criterion is

$$|BNCR| < P \quad (6)$$

Where  $P$  is termination parameter and  $BNCR$  is block noise cancellation ratio and defined as

$$BNCR = 10 \log \left[ \frac{\delta_x^2 - (\delta_d^2 - \delta_v^2)}{\delta_x^2} \right] \quad (7)$$

Where  $\delta_x^2$  is power of reference signal and  $X_s(r_b, c_b)$  can be related as

$$\delta_x^2 = \sum_{k=1}^{M+N-1} \sum_{l=1}^{M+N-1} \frac{[X_s(k, l) - X_{mean}]^2}{[L+(M-1)-1][L+(N-1)-1]} \quad (8)$$

the term  $\delta_d^2$  is the power of the primary input signal  $d_s(r_b, c_b)$  and can be expressed as

$$\delta_d^2 = 1/(L-1)^2 \sum_{r_b=1}^L \sum_{c_b=1}^L [d_s(r_b, c_b) - d_{mean}]^2 \quad (9)$$

the term  $\delta_e^2$  is the power of the error signal  $e_s(r_b, c_b)$  and can be expressed as

$$\delta_e^2 = 1/(L-1)^2 \sum_{r_b=1}^L \sum_{c_b=1}^L [e_s(r_b, c_b) - e_{mean}]^2 \quad (10)$$

In (8)-(10)  $X_{mean}$ ,  $d_{mean}$ , and  $e_{mean}$  stand for the means of  $X_s$ ,  $d_s$ , and  $e_s$ , respectively.

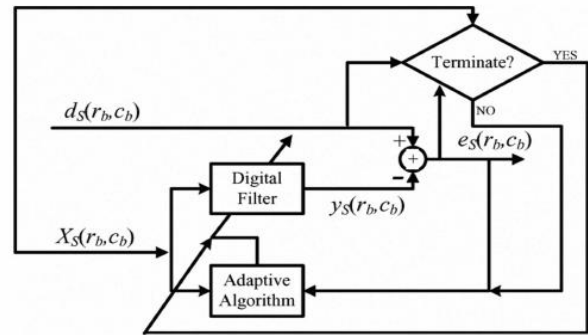

Fig-3. Adaptive filter with weight training mechanism

#### 3.2 Block Adaption phase

Once the suitable weight matrix  $W_{T_a}$  in the weight training phase is found, this weight matrix is treated as the initial weight matrix  $W_i$  in the block-adapting phase. In this phase, the original noisy image is processed according to the TDBLMS algorithm [10] again for the noise cancellation

### IV. PROPOSED EXPERIMENTAL WORK

An adaptive filter has two phase weight training and weight adaption phase. In this work we proposed a new two dimensional adaptive filter that will process a colour image. First an image is convert in to frames of three colours they are red, green, blue of different intensity level then these frames will be process by two dimensional block recursive least mean square filter individually. Output of three parallel filters will combine at the last to remove noise from original image

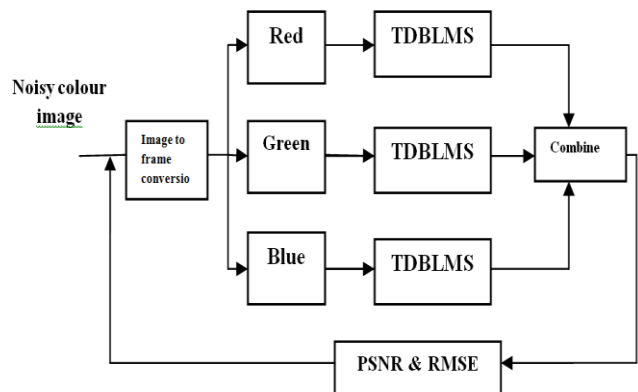

Fig-4 Two dimensional adaptive filter for color image Equations

They should be numbered consecutively throughout the text. Equation numbers should be enclosed in parentheses and flushed right. Equations should be referred to as Eq. (X) in the text where X is the equation number. In multiple-line equations, the number should be given on the last line.

$$y_i(N) = \sum_{n=0}^{m-1} w_n(N) b_n(N) = \sum_{n=0}^{m-1} b_n^*(N) r_i(N) \cdot b_n(N) \quad (1)$$

### V. RESULTS

The primary input signal with a dimension of 400x400 in the simulation phase is created by adding a Gaussian noise with

zero mean and 0.02 variance to the ideal image Baboon with 400 color-levels in Fig. 4(a) shows the primary input image with a dimension of 400 x 400 and Fig. 4(b) shows the noisy primary input image with an SNR of 0 dB. The convergence factor is  $4.5 \times 10^{-7}$ . For digital filter, the RLMS filter is chosen to convolved the reference image and the filter window with a dimension of 2 x 2 ( $M = 2, N = 2$ ).

Figure 5 (a) Primary input image Baboon with a dimension of 400x400 (b) Noisy primary input image with SNR= 0 dB In order to observe the effect of block size on the performance, four different block sizes of 4 x 4 ( $L = 4$ ), 8 x 8 ( $L = 8$ ), 16 x 16 ( $L = 16$ ), and 32 x 32 ( $L = 32$ ) are simulated. Table 1 lists the performance comparison.

Fig. 6(a) is the restored image for the proposed adaptive filter where the termination parameter P is chosen to be -10 dB. Fig. 6(b) is the restored image for the proposed adaptive filter where the termination parameter P is chosen to be -10 dB The simulation results indicate that the proposed adaptive filter achieves a better performance;

### VI. CONCLUSION

An adaptive filter for color image with weight-training mechanism was proposed in this paper. First, a suitable weight matrix was found by scanning the image block-by-block and updating the weight matrix for each until the termination criterion is reached in the weight-training phase. Process runs parallel for three colors. The simulation performed on the noisy image Baboon with a dimension of 400x400 with an SNR of 0 dB shows that this approach can achieve the PSNR's of 20.6095, 20.6112, 20.6520 and 20.4283 for the block sizes of 4 x 4, 8 x 8, 16 x 16, and 32 x 32, respectively. The proposed method provides better image. The proposed has been tested on well-known benchmark images, where their PSNR and visual results show the superiority of the proposed technique over the conventional techniques.

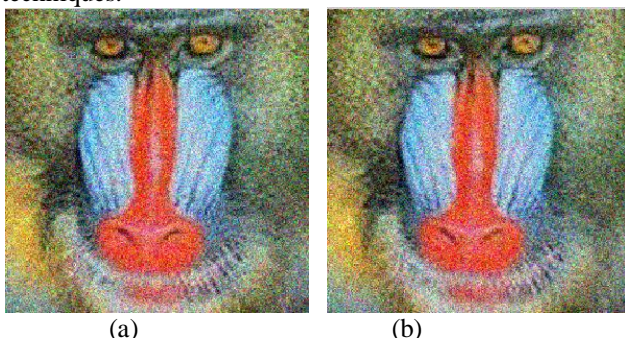

Figure 6 simulation result of predicted image (a) predicted image with  $(L, M, N) = (4, 2, 2)$ . (b) Predicted image with  $(L, M, N) = (8, 2, 2)$ . (c) Predicted image with  $(L, M, N) = (16, 2, 2)$ . (d) Predicted image with  $(L, M, N) = (4, 2, 2)$

Block size	Proposed work for color image		TDBLMS for gray image
	PSNR(dB)	RMSE(dB)	PSNR(dB)
4x4	20.6095	23.7721	26.7341
8x8	20.6112	23.7672	20.8253
16x16	20.6520	23.6559	16.2340
32x32	20.4283	24.2732	14.4419
